How many ways we can fetch OR retrieve the Collection Objects ?

* There are 6 ways to retrieve the Collection Objects which are as follows :

1) By using Iterator() method of respective class. [JDK 1.0V]

2) By using printers for loop. [JDK 1.0V]

3) By using for-each loop. [JDK 1.5V]

4) By using Enumeration<E> interface. [JDK 1.0V]

5) By using Iterator<E> interface. [JDK 1.2V]

6) By using ListIterator<E> interface. [JDK 1.2V]

7) By using forEach(Consumer<? > cons) [JDK 1.8V]

8) By using Spliterator. [JDK 1.8V]

9) By using Method Reference. [JDK 1.8V]

Retrieve the Collection Object by using all 9 ways :

Enumeration<E> interface :

It is a predefined interface available in java.util package from JDK 1.0 onwards(Legacy interface).

We can use Enumeration interface to fetch or retrieve the Objects one by one from the Collection because it is a cursor.

We can create Enumeration object by using elements() method of the legacy Collection class. Internally it uses anonymous inner class object internally.

public Enumeration<E> elements();

Enumeration interface contains two methods :

1) public boolean hasMoreElements() : It will return true if the collection object is available in the current index position.

2) public E nextElement() : It will return collection object we return type is Object[0] and move the cursor to the next index.

Note : It will only work with legacy Collections classes.

Internal Working :

```
Vector<String> listOfCity = new Vector<>();
        listOfCity.add("Hyderabad");
        listOfCity.add("Delhi");
        listOfCity.add("Pune");
        listOfCity.add("Mumbai");

        Enumeration<String> ele = listOfCity.elements();
        while(ele.hasMoreElements()) {

            System.out.println(ele.nextElement());
        }
```

Iterator<E> :

It is a predefined interface available in java.util package available from 1.2 version.

It is used to fetch/retrieve the elements from the Collection in forward direction only because it is also a cursor. It is a universal cursor.

It is using inside most cases if JK class implements from Iterator<E>.

public Iterator<E> Iterator();

Example :

```
Iterator it = listOfCity.iterator();
```

Now, Iterator interface has provided two methods

```
public boolean hasNext() :
```

Return true, the element is available in the current position or not, if available it will return true otherwise it will return false.

```
public Object next() : It will return the collection object and move the cursor to the next element object.
```

```
ListIterator<E> interface :
```

It is a predefined interface available in java.util package and it is the sub interface of Iterator available from JDK 1.2v.

It is used to retrieve the Collection object in both the direction i.e in forward direction as well as in backward direction. Hence this interface is called cursor interface.It is derived from Its class implements from ListIterator interface

It works on the basis of index. (Will work only for List interface)

```
public ListIterator listIterator();
```

Example :

```
ListIterator it = listOfCity.listIterator();

1) public boolean hasNext()
2) public Object next()
3) public boolean hasPrevious()
4) public Object previous()
```

Note :- Apart from these 4 methods we have add(), set() and remove(), nextIndex() and previousIndex() method in ListIterator interface.

forEach(Consumer<? > cons) :

forEach() method is available from JDK 1.8V.

This forEach() method iterate the elements from the source

This forEach(Consumer<? > cons) method is available in java.lang.Iterable interface, It is added as a default method inside Iterable interface.

The forEach(Consumer<? > cons) method of Iterable interface internally uses for each loop.

How forEach(Consumer<T>) method works internally ?

```
Case 1;
-------
By using Anonymous inner class :

    package com.rssl.collection_retrieval_demo;

import java.util.Vector;
import java.util.function.Consumer;

public class ForEachMethodInternalWorkingDemo1 {

    public static void main(String[] args)
    {
        Vector<String> listOfCity = new Vector<>();
        listOfCity.add("Hyderabad");
        listOfCity.add("Vizag");
        listOfCity.add("Delhi");
        listOfCity.add("Mumbai");

        //Anonymous inner class
        Consumer<String> cons = new Consumer<String>()
        {
            @Override
            public void accept(String city)
            {
                System.out.println(city);
            }
        };

        listOfCity.forEach(cons);
    }
}
```

```
Case 2 :
--------
By Using Lambda Expression :

package com.rssl.collection_retrieval_demo;

import java.util.Vector;
import java.util.function.Consumer;

public class ForEachMethodInternalWorkingDemo2 {

    public static void main(String[] args)
    {
        Vector<String> listOfCity = new Vector<>();
        listOfCity.add("Hyderabad");
        listOfCity.add("Vizag");
        listOfCity.add("Delhi");
        listOfCity.add("Mumbai");

        //Lambda Expression
        Consumer<String> cons = (City  -> System.out.println(City.toUpperCase());
        listOfCity.forEach(cons);

        //Passing Lambda directly to forEach method
        listOfCity.forEach(City  -> System.out.println(City.toUpperCase());
    }
}
```

8) Spliterator<E> interface :

It is a predefined interface available in java.util package from java 1.8 version.

It is a cursor through which we can fetch the elements from the Collection [Collection, array, Stream]

It is the combination of hasNext() and next() method for Iterator interface as well as

forEachRemaining() method.

It is using forEachRemaining(Consumer<T> cons) method for fetching the elements which is internally using do-while loop

9) By using Method Reference : [Introduction Only]

* It is an improvement over lambda expression, By using method reference we can refer any existing method available in the our project OR Java library.

```
//Program to fetch the Collection Object by using 9 ways :

package com.rssl.collection_retrieval_demo;

import java.util.Enumeration;
import java.util.Iterator;
import java.util.ListIterator;
import java.util.Vector;

public class PossibleWaysToFetchFromACollectionObjects
{
    public static void main(String[] args)
    {
        Vector<String> listOfCity = new Vector<>();
        listOfCity.add("Hyderabad");
        listOfCity.add("Vizag");
        listOfCity.add("Delhi");
        listOfCity.add("Mumbai");

        System.out.println("1) By using toString() Method :");
        System.out.println(listOfCity.toString());

        System.out.println("2) By using Ordinary for loop :");

        for(int i=0; i<listOfCity.size(); i++)
        {
            System.out.println(listOfCity.get(i));
        }

        System.out.println("3) By using for each loop :");

        for(String city : listOfCity)
        {
            System.out.println(city);
        }

        System.out.println("4) By using Enumeration<E> interface :");
        Enumeration<String> ele = listOfCity.elements();

        while(ele.hasMoreElements())
        {
            System.out.println(ele.nextElement());
        }

        System.out.println("5) By using Iterator<E> interface :");

        Iterator<String> it = listOfCity.iterator();
        it.forEachRemaining(city -> System.out.println(city));
        while(it.hasNext())
        {
            System.out.println(it.next());
        }

        System.out.println("6) By using ListIterator<E> interface :");
        ListIterator<String> lstIt = listOfCity.listIterator();

        System.out.println("6) FORWARD DIRECTION :");
        while(lstIt.hasNext())
        {
            System.out.println(lstIt.next());
        }

        System.out.println("6) BACKWARD DIRECTION :");
        while(lstIt.hasPrevious())
        {
            System.out.println(lstIt.previous());
        }

        System.out.println("7) By using forEach(Consumer<T> cons) method :");
        listOfCity.forEach(city -> System.out.println(city));

        System.out.println("8) By using Spliterator interface :");

        Spliterator<String> spliterator = listOfCity.spliterator();
        spliterator.forEachRemaining(city -> System.out.println(city));

        System.out.println("9) By using Method Reference :");
        listOfCity.forEach(System.out::println);
    }
}
```

Working with List interface Specific classes :

As we know, in List interface we have 4 implemented classes which are as follows :

1) Vector<E>
2) Stack<E>
3) ArrayList<E>
4) LinkedList<E>

```
Vector<E> :
-----------
public class Vector<E> extends AbstractList<E> implements List<E>, Cloneable, Serializable, RandomAccess
{
* It is an implemented legacy class of List<E> interface available from JDK 1.0V.
* It is similar to ArrayList<E> but synchronized and thread safe.
* It stores the Objects based on the index position.
* It internally uses "Dynamic Array" data structure.
* Vector is thread safe and synchronized.
* Vector capacity is 10, next capacity would be 20.
* Methods are synchronized so, performance wise Vector is not good.
* Vector is the only class which provides three capability.
* Iterator is Fail Fast Iterator.
* hashCode() & equals() method are overridden.
* Vector is the only class which is available in every programming environment.
* Vector implements from Serializable, RandomAccess, Cloneable and List<E>.

Constructors :

1) Vector()
```

We have 4 types of Constructors in Vector

```
1) Vector<e1> e new Vector();
   It will create the vector object with default capacity is 10.
   [Internally Object array]

2) Vector<e1> e new Vector(int initialCapacity);
   Will create the vector object with user specified capacity.

3) Vector<e1> e new Vector(int initialCapacity, int capacityIncrement);
   Here, initial capacity is 10, next capacity would be 20.
   Methods are synchronized so, performance wise Vector is not good.
   Vector is the only class which provides three capability.
   Iterator is Fail Fast Iterator.
   hashCode() & equals() method are overridden.
   Vector is the only class which is available in every programming environment.
   Vector implements from Serializable, RandomAccess, Cloneable and List<E>.

Constructors :

1) Vector()
```

We have 4 types of Constructors in Vector

```
1) Vector<e1> e new Vector();
   It will create the vector object with default capacity is 10.
   [Internally Object array]

2) Vector<e1> e new Vector(int initialCapacity);
   Will create the vector object with user specified capacity.

3) Vector<e1> e new Vector(int initialCapacity, int capacityIncrement);
   Here, initial capacity is 10, next capacity would be 20.

   Initially it will create the Vector Object with initial capacity 10 and then when the capacity will be full then
   incremented by 5 as the next capacity would be 165, 110 and so on.

4) Vector<e1> e new Vector(Collection c);
   We can achieve these coupling
```

//Programs on Vector :

```
package com.rssl.vector_demo;

import java.util.Vector;

//Add all the elements of Vector

public class VectorDemo1
{
    public static void main(String[] args)
    {
        Vector<Integer> listOfNumbers = new Vector<>();

        listOfNumbers.add(100);
        listOfNumbers.add(200);
        listOfNumbers.add(300);
        listOfNumbers.add(400);
        listOfNumbers.add(500);

        Integer num = 0;

        for(Integer number : listOfNumbers)
        {
            num += number;
        }

        System.out.println("Sum of Vector elements :"+num);
    }
}
```

```
package com.rssl.vector_demo;

import java.util.Collections;
import java.util.Vector;

//Custom Object

record ProductInteger(Integer id, String name, Double price) implements Comparable<ProductInteger>
{
    @Override
    public int compareTo(ProductInteger o)
    {
        return Double.compare(this.price(), o2.price());
    }
}

public class VectorDemo2
{
    public static void main(String[] args)
    {
        Vector<ProductInteger> listOfProducts = new Vector<>();

        listOfProducts.add(new ProductInteger(111, "Mobile", 340000));
        listOfProducts.add(new ProductInteger(222, "Laptop", 960000));

        System.out.println("Original Data :");
        for(ProductInteger product : listOfProducts)
        {
            System.out.println(product);
        }

        Collections.sort(listOfProducts);

        System.out.println("Sorted Product Object based on the Price :");
        for(ProductInteger product : listOfProducts)
        {
            System.out.println(product);
        }
    }
}
```

```
package com.rssl.vector_demo;

import java.util.Vector;

//Vector Constructors
public class VectorDemo3
{
    public static void main(String[] args)
    {
        Vector<Integer> listOfNumber = new Vector<>(30, 20);

        System.out.println("Initial Capacity is :"+listOfNumber.capacity());

        for(int i=0; i<=100; i++)
        {
            listOfNumber.add(i);
        }

        System.out.println("After adding 100 elements :");
        System.out.println("Size is :"+listOfNumber.size());
        System.out.println("Capacity is :"+listOfNumber.capacity());

        listOfNumber.add(999);
        System.out.println("After adding 999 element :");
        System.out.println("Size is :"+listOfNumber.size());
        System.out.println("Capacity is :"+listOfNumber.capacity());
    }
}
```

Collections.max() & Collections.min() both methods are using Collection interface as a parameter.

```
public default sort(Comparator<? > com)

* A default method inside List<E> interface from JDK 1.8V to provide backward compatibility.

* It accepts Comparator<? > as a parameter so we can provide custom sorting.
```

```
    package com.rssl.vector_demo;

import java.util.Collections;
import java.util.Vector;

public class VectorDemo4
{
    public static void main(String[] args)
    {
        Vector<Integer> listOfNumber = new Vector<>();
        listOfNumber.add(67);
        listOfNumber.add(34);
        listOfNumber.add(89);
        listOfNumber.add(12);
        listOfNumber.add(29);

        System.out.println("Original Data : "+listOfNumber);

        System.out.println();

        Collections.sort(listOfNumber);
        System.out.println("Sorting in Ascending Order : "+listOfNumber);

        /*Old Approach
        Collections.sort(listOfNumber, (o1,o2)-> o1.compareTo(o2));
        System.out.println("Sorting in Descending Order : "+listOfNumber);
        */

        listOfNumber.sort((o1,o2) -> o2.compareTo(o1));
        System.out.println("Sorting in Descending Order : "+listOfNumber);

        System.out.println("Maximum element is :"+Collections.max(listOfNumber));
        System.out.println("Minimum element is :"+Collections.min(listOfNumber));
    }
}
```
